tion

**Me:** Hey Siri, order me a Pizza

**Siri:** *(After a short break that nearly drains your whole battery)* Ok, I'm calling your mother...

**Me:** Wait! Why would you do this!?

**Siri:** This is the 5th time you ordered Pizza this week.

What do we want from our model?

- ① Why did failed predictions fail?
- ② Why did correct predictions succeed?
- ③ Why is my model uncertain about a prediction?

special importance:  
setting a model *live*, where it's not *prelabeled*

Interpretations must be ...

- *human-readable*
- reproducible (same input + same model  $\rightarrow$  same output)
- **model agnostic**, meaning they can work with any (black-box) model

Difficulties:

- Models can be huge (millions of weights)
- Inputvectors can be huge (e.g. images)
- Some models are too complex by its structure to be readable, (e.g. neural networks)

# Example

Desired output of a "Atheism"-Classifier

Classifier  
Explan-  
ation

Applis

Intro

LIME

SP-  
LIME

Example:  
Traffic  
Sign  
Recogni-  
tion

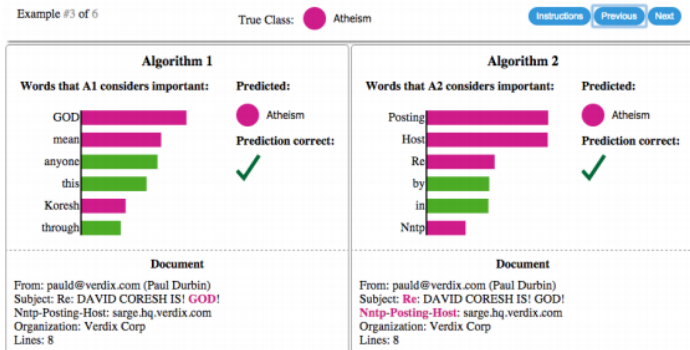

Figure: LIME-Text: predicting "Atheism" for given text

Both algorithms predict correct - yet Algorithm 2 has strange reasons.

trusting predictions  $\neq$  trusting a model

What do we want?

- ➊ get an *overview* of our Model
- ➋ compare models in reasonable time
- ➌ proove correctness & flaws of a model
- ➍ improve our models

Several topics which benefit from machine learning, but need special care:

- ① Terrorism-detection
- ② Medical diagnosis & prescriptions
- ③ Fraud-detection

Noone will buy a model, if you can't prove that it's performing reasonable predictions.

There are several issues, at which explanations can help you improve your models:

- ❶ Filtering of Features
- ❷ Find overfitted weighting of features
- ❸ Find Links in Classification (Similiar Classes and Features)

Gaining insights from explanations can help you improve your model!

## What do we want:

- Human Readable Model Explanation
- For Every Classifier
- For Every Input

**features  $\neq$  human readable**

To gain *readability*:

- show influence relative to each other, not as numbers
- only show most important features
- use *superpixels* instead of pixels

Let:

- ❶  $G$  be any possible explanation model
- ❷  $g$  be our explanation Model
- ❸  $\Omega(g)$  the complexity of our Model
  - Weights in a regressions model
  - Depth of an decisiontree
  - Number of trees in a random forest
- ❹  $f : Features \rightarrow Class$  be the real classification
- ❺  $\Pi_x(z)$  as proximity-measure from  $x$  to  $z$
- ❻  $\mathcal{L}(f, g, \Pi_x)$  measure of un-faithfulness of  $g$  compared to  $f$  given the proximity  $\Pi_x$

Wanted:

$$\xi(x) = \operatorname{argmin}_{g \in G} \mathcal{L}(f, g, \Pi_x) + \Omega(g)$$

Read:

- We want for every input  $x$
- an explanation(-model)
- where complexity of  $g$  and the failure of  $g$  are minimal
- given a set of possible explanations  $G$

We do so by picking samples  $x'$  as subsets from an input  $x$  and optimizing our model  $g$
